## PREPAID FIXED QUANTITY ACCESS TO WEB SERVICES

Technical Field

The present invention relates generally to computer systems and more particularly to prepaid fixed quantity access to web services.

Background of the Invention

Internet service providers (ISP's) require a customer to open a customer account prior to gaining access to the Internet services provided by the ISP's. A customer opens such an account by contacting an ISP via a computer connection, a telephone connection, a cable connection or a wireless connection. The customer is required to provide user identification (ID) information and to select a password. The ISP may then transmit certain data and software to be downloaded onto the customer's machine.

ISP's generally provide two types of payment schemes for customers. In the first type of payment scheme, a customer is given an unlimited quantity of access to the Internet services provided by the ISP. The customer is billed at periodic intervals, such as once a month or once a year. The customer is either sent a bill requesting payment or may be assessed a credit card charge for the costs of Internet access provided by the ISP.

In the second type of the payment scheme, a customer is charged on a per usage basis. The ISP monitors usage of the Internet services by the customer and calculates costs based upon the quantity of usage by the customer. These costs are then either billed to the customer or reflected in a credit card charge that is assessed to the customer. For example, the customer may be charged in a current month for the Internet usage in a previous month.

Such conventional ISP account and payment schemes do not work well for some customers. For example, these account and payment schemes do not work well for one time customers. A one time customer has to create an account and pay for an entire billing period of service. The account and payment schemes also do not work well for mobile customers. Mobile customers often use a number of different devices at a number of different locations. The multiple devices available to a customer may not

5 have the requisite programs and code to access an ISP from the login site. Moreover, it  
may be difficult to access certain ISP's from remote locations outside a subscriber area.

10 Summary of the Invention

5 The present invention provides an approach to providing web services that is  
well-adapted for a variety of different users, including one-time users and multiple users.  
The present invention provides prepaid fixed quantity access to web services. The web  
15 services are accessed by way of accounts that have associated quantities of service. For  
example, an account may be allocated ten dollars worth of web access. The account has  
10 an associated account identifier and is not necessarily tied to a particular user. The user  
may access the Internet services until the fixed amount of web services have been  
20 consumed.

The user may be provided with the account identifier on a plastic card. The user  
may access a designated web page or call a designated phone number to gain access to  
25 the Internet services provided by the ISP. The user is prompted for the account  
identifier and, perhaps, some authentication data before the user is granted access to the  
Internet services.

30 In accordance with a first aspect of the present invention, a method is practiced  
in a computer network. In accordance with this method, an account is provided for  
20 access to Internet services from an ISP. The account has an associated fixed monetary  
value. The account is monitored to determine the quantity of usage of the account and  
35 the monetary value of the account is debited based upon the quantity of usage of the  
account. The account may, in some instance, not be associated with any user. A user  
may be refused access to the Internet services via the account when the monetary value  
40 of the account is less than a threshold amount.

In accordance with a further aspect of the present invention, a prepaid amount of  
web services are provided and available to a client. The client is enabled to use the web  
45 services, and the amount of web services available to the client is debited based on how  
much the client used the web services.

5 In accordance with another aspect of the present invention, a physical object that includes information regarding a prepaid amount of services from an ISP is provided to a user. A request to access the services provided by the ISP is received from the user.  
10 At least some of the information included in the physical object is received from the user, and, in response, the services are provided to the user until the prepaid amount of services have been consumed by the user.

15 In a distributed environment that has multiple login sites, a web services account is provided for web services. The web services account is authorized for a fixed amount of web services. A user is enabled to access the web services via an account from a first  
20 of the login sites and from a second of the login sites.

25 In accordance with an additional aspect of the present invention a computer system includes a web service provider for providing web services to clients. The computer system also includes an account manager for creating accounts for accessing web services provided by the web service provider. Each account is allocated a prepaid  
30 fixed amount of the web services. The computer system has a monitor for monitoring usage of the accounts and debiting accounts based on usage.

#### Brief Description of the Drawings

35 An illustrative embodiment, which is consistent with the principles of the present invention, will be described below relative to the following drawings.

40 FIGURE 1 depicts a computing environment that is suitable for practicing the illustrative embodiment.

45 FIGURE 2 depicts a block diagram of components of the client device of Figure 1.

50 FIGURE 3 depicts a block diagram of components of the web server of Figure 1.

FIGURE 4 depicts the format of a database that holds account information.

FIGURE 5 depicts an example of an ISP card that is provided to a customer.

FIGURES 6A and 6B illustrate a smart card that may be used with the illustrative embodiment.

FIGURE 7 is a flow chart depicting the steps that may be performed to receive payment for gaining access to an account for ISP services.

5           FIGURE 8 is a flow chart that illustrates the steps performed for a client to gain access to Internet services provided by an ISP.

10           FIGURE 9 is a flow chart illustrating the steps that are performed for a client to login to the web server of the ISP.

5           FIGURES 10A and 10B illustrate an example of a window that prompts a client for login information.

15           FIGURE 11 is a flow chart illustrating steps that are performed to monitor client usage of an account.

10           FIGURE 12 illustrates an example of a mobile user using multiple devices at multiple sites to gain access to the web server of an ISP.

#### 20           Detailed Description of the Invention

25           The illustrative embodiment, which is consistent with the principles of the invention, provides prepaid Internet services. A client is provided access to a prepaid account associated with a given quantity of Internet services. In the illustrative embodiment, the account is not associated with the user. The account may be shared by multiple users. Moreover, a user may access the account from multiple login sites and from multiple machines. The value of the account is debited based upon usage.

30           When a client (i.e. a user) desires to access the Internet services, the client is prompted to provide an account identifier for the prepaid account. For security purposes, the client may also be prompted to provide authorization data, such as a personal identification number (PIN). The client is then granted access to the Internet services, and the usage of the Internet services by the client is monitored to continuously update the quantity of Internet services available in the account. The client may be provided with a credit card sized card that contains the account identifier and other information necessary to access the Internet services provided by the ISP.

45           The illustrative embodiment provides an approach to accessing Internet services that is especially well adapted for a one-time client. The one-time client need only obtain an account identifier and then use that account identifier to gain access to the ISP services. Accounts may be available in different service quantities so that a one-time

5 client may select an account having a quantity of services that is appropriate for the anticipated usage.

10 The illustrative embodiment also provides a useful approach for a mobile client. The mobile client need not be concerned about which device the mobile client is using to gain access to the Internet services. Moreover, the mobile client need not be concerned with the location from which the client seeks to gain access to Internet services. The mobile client needs to simply contact a given web site or call a designated ISP telephone number to gain access to the Internet services.

In order to help clarify the discussion below, it is helpful to define a few terms.

10 An "Internet service provider (ISP)" provides Internet access to client.

20 "Web services" are services that are provided by a provider over a network, such as the Internet, an intranet or an extranet. The network may, for example, adopt the TCP/IP protocol suite.

25 "Internet services" are services provided by an ISP over the Internet. A primary example of Internet services is access to the Internet.

A "web server" is a server that provides web services. The web server is part of a network, such as the Internet, an intranet or an extranet.

30 Figure 1 depicts a computing environment 10 that is suitable for practicing the illustrative embodiment. A client uses a client device 12 to contact a web server 14 that is part of a network 16. In the illustrative embodiment, it is assumed that the web server 14 is part of the Internet. Nevertheless, those skilled in the art will appreciate that the web server 14 may also be part of an intranet, an extranet or another computer network. The present invention is not limited to being practiced within the Internet but also works with other networks and other networks that employ connectionless protocols. Moreover, in some embodiments, the client and server may reside on the same machine.

40 The client device 12 may be any of a number of different types of devices. For example, the client device 12 may be a desktop computer system, a laptop computer system or even a palmtop computer system. The client device 12 may be a network computer, an intelligent television set, a pager or other device that is able to communicate with the web server 14 and create an appropriate connection. The client

5 device 12 may access the web server 14 by using a dial-up network program or by creating a connection via a web browser.

10 Figure 2 depicts the client device 12 in more detail. In the example depicted in Figure 2, the client device 12 is a computer system. The client device 12 shown in  
5 Figure 2 includes a central processing unit (CPU) 14 for executing computer program instructions and overseeing operation of the client device. The client device 12 of  
15 Figure 2 includes a video display 16, a keyboard 18 and a mouse 20. The client device 12 may also include a modem 32. The modem may be a conventional data modem, a cable modem or a wireless modem. A network adapter 30 may be included in the client  
20 device 12 to connect the computer system to a local area network.

25 The client device 12 may include primary storage 22 and secondary storage 24. The primary storage 22 and secondary storage 24 may include any of the number of well-known storage devices and computer-readable mediums. A primary storage 22 may hold dial-up networking support 26 and/or a web browser 28.

30 Those skilled in the art appreciate that the depiction of the client device 12 in Figure 2 is intended to be merely illustrative and not limiting of the present invention. Configurations that differ from the configuration depicted in Figure 2 may be utilized. For example, different peripheral devices may be utilized and not all of the components shown in Figure 2 are required to practice the present invention.

35 Figure 3 depicts the major logical components of the web server 14. The web server includes web server support 40 for enabling the client to gain access to web or Internet services. The web server support 40 includes support for the TCP/IP protocol suite, HTML, or the Java™ platform and the like. Java is a trademark and/or a registered trademark of Sun Microsystems, Inc. in the United States and in other  
40 countries. The web server support 40 may include a number of HTML documents for web pages that are forwarded to clients. The web server 14 also includes a database 42 for holding account information. This database 42 will be described in more detail  
45 below. A time usage monitor 44 is provided in the web server 14 to monitor usage of the Internet services on a per account basis. This time usage monitor 44 will also be  
50 described in more detail below.

5           The web server 14 creates a number of different accounts. These accounts may  
be all associated with a fixed quantity of web services, or the accounts may be  
associated with different quantities of web services. For example, some accounts may  
10           be associated with ten dollars worth of services, whereas other accounts may be  
5           associated with five dollars of services. Similarly, accounts may be associated with five  
hours, ten hours and fifteen hours of service.

15           The quantity of services associated with an account may be expressed as a value  
of time, monetary value or other metric. Those skilled in the art will appreciate other  
methods may be used to quantify amounts of service or web access.

20           The database 42 holds information regarding each account, including the  
quantity of service associated with the account. Figure 4 shows an example of the  
database 42. The database 42 includes an entry 50 for each account. An account  
number or account identifier 52 is associated with each account. The value of this  
25           account number 52 is stored within the database 42 for each account. Information  
15           regarding the time that has been consumed 54 on the account is also stored in the  
database. Information regarding the time that is left 56 in the account is also stored  
within the database 42. For example, as shown in Figure 4, account ABC was originally  
30           allocated three hours of Internet access. An hour of the three hours has been consumed  
and two hours remain. Alternatively, a record of the total time purchased and the time  
20           used may be kept in the database 42. As another alternative, a record of the total time  
purchased and the time remaining may be kept in the database 42.

35           For client convenience, ISP cards, such as the ISP card 60 depicted in Figure 5,  
may be utilized. These ISP cards are preferably small enough and light enough to be  
easily carried by a client. Preferably, the ISP card is made of a durable material, such as  
40           25           paper or plastic. The ISP card may contain information such as an account number of  
identifier 62 (e.g. "ABC"). The ISP card may also include an indicator 64 of the amount  
of services associated with the account. In the example depicted in Figure 5, the ISP  
45           card is for an account that is prepaid for five hours of Internet access. The ISP card 60  
may also include information 63 regarding a telephone number that is to be called to  
30           gain access to the account.

5 Alternatively, the user may be provided with a smart card such as shown in  
Figures 6A and 6B. The smart card may comply with the ISO-7816 standard or the  
EMV integrated circuit card specification. Preferably, the smart card complies with the  
10 JavaCard 2.1 specification as defined by Sun Microsystems, Inc. of Palo Alto,  
5 California. The JavaCard 2.1 specification requires that the secure token device be  
capable of running programs written in the Java programming language. Those skilled in  
15 the art will appreciate that the smart card need not run the Java programming language.  
Those skilled in the art will appreciate that the smart card need not run the Java  
programming language to practice the present invention.

10 Figure 6A shows the front side of the smart card 66, that which includes a  
number of electrical contacts 70 for electrical communication with a microprocessor that  
20 is embedded in the smart card 66. A substrate 68 of a suitable material, such as plastic,  
forms the core of the smart card. A region 72 may be provided on the front side be to  
signed by the holder of the smart card or to hold other textual information. The smart  
25 card 66 may include a magnetic strip 74 on the rear side, such as shown in Figure 6B, to  
hold information that is readable by a magnetic strip reader. The smart card may hold  
electronic currency tokens that are used for a payment to obtain a prepaid account on  
30 behalf of the holder of the smart card.

Payment for accounts may take many forms. A corporation may, for example,  
20 make a lump sum payment for a large number of accounts. These accounts may be  
distributed for promotional purposes. Moreover, these accounts may be distributed to  
35 employees of the corporation for Internet access. Still further, ISP cards may be sold in  
vending machines to enable a user to gain access the Internet services provided by the  
ISP. ISP cards may be provided for a number of different ISP's. Those skilled in the art  
40 will appreciate that a number of other payment options may be used.

Regardless of the payment scheme, the general pattern of payment and activation  
of accounts follows the flow chart depicted in Figure 7. The purchaser will be prompted  
45 for payment (step 80 in Figure 7). The ISP receives payment for the account (step 82 in  
Figure 7) and activates the account (step 84 in Figure 7). The payment may entail  
30 transferring electronic currency tokens from a smart card to the ISP. The activation of  
the account may occur at the time of payment or at the time when a user first attempts to  
50

5 use the account. The activation make the account ready for use by a client. The  
purchaser is given the account identifier and authorization data (step 86 in Figure 7). In  
the illustrative embodiment, the purchaser is given an ISP card that holds the account  
10 identifier and is provided with information regarding a PIN or other authorization data.  
5 Those skilled in the art will appreciate that third parties may receive payment on behalf  
of the ISP. Furthermore, third parties may activate the account and tender the ISP card  
in some embodiments.

15 Figure 8 provides an overview of the steps that are performed for a client to  
utilize Internet services in the illustrative embodiment. Initially the client contacts the  
20 web server 14 (step 90 in Figure 8). As mentioned above, this may be achieved using  
dial-up networking software 26 from the client device 12 or by placing a call and using a  
web browser 28. The client then performs the steps necessary for login (step 92 in  
Figure 8). Figure 9 provides a flow chart of the steps that are performed during login.  
25 The login begins with the web server 14 prompting the client for an account identifier,  
such as an account number (step 100 in Figure 9). The web server 14 may generate a  
web page 120, such as shown in Figure 10A. The web page 120 may be stored as an  
HTML document on the web server. The web page 120 includes a textual prompt 122  
30 that asks the client to enter an account number for an account within text box 124. The  
client may type in the account number within the text box 124 and hit a return key so  
20 that the account identifier is received by the web server 14 (step 102 in Figure 9). The  
web server 14 checks whether the account identifier that is provided by the client is valid  
or not (step 104 in Figure 9). The database 42 holds all the valid account identifiers. If  
35 the account identifier is not valid, the client is denied access (step 112 in Figure 9).  
However, if the account identifier is valid, the web server 14 checks whether the account  
40 has expired or not (step 106 in Figure 9). The accounts may have fixed life cycles such  
that they expire after a given period of time, or the value of the account may have been  
totally consumed. For example, an account may be valid for only a single year. Those  
45 skilled in the art will appreciate the order of performance of steps 104 and 106 may be  
reversed. If the account has expired, the client is denied access (step 112 in Figure 9).

5           If the account identifier provided by the client is valid, the client is prompted for authentication data (step 108 in Figure 9). Figure 10B shows an example of a web page 121 that may be provided by the web server 14 to prompt the client to enter authentication data. The web page 121 includes a textual prompt 126. In the example shown in Figure 10B, the authentication data is a PIN (i.e. a six character alpha-numeric code). The web page 121 may, alternatively, request that the client provide a password or other shared secret that constitutes a type of authentication data. The web page 121 includes a text box 128 in which the authentication data may be entered. The resulting authentication data is received at the web server 14 (step 110 in Figure 9). The web server 14 checks whether the authentication data is valid or not (step 114 in Figure 9). If the authentication data is not valid, the client is denied access to the Internet services provided by the ISP via the web server 14. On the other hand, if the authentication data is valid, the client is granted access to the Internet services provided by the ISP via the web server 14 (step 115 in Figure 9).

15           Once the client has logged-in to the web server 14 (step 92 in Figure 8), the web server 14 then provides the client with Internet services (step 94 in Figure 8). While the client is using the Internet services, the web server 14 monitors usage (step 96 in Figure 8).

20           Figure 11 depicts the steps that are performed to monitor usage of the Internet services by a client (see step 96 in Figure 8). As was mentioned above, the web server 14 maintains the database 42 to monitor the time used and the time remaining for a given account. The steps shown in Figure 11 are performed at periodic intervals such as once a minute or once every five minutes. At each interval, the time used for the account is incremented (step 130 in Figure 11). The time left or remaining for the account is decremented for the same quantity. For example, if the steps are performed every five minutes, in step 130 of Figure 11, the time used is incremented by 5 minutes and in step 132 of Figure 11, the time remaining is decremented by 5 minutes. The time usage monitor 44 (see Figure 3) of the web server 14 then checks whether there is any time remaining for the account in step 134, Figure 11. If there is not any time left, the client is advised and services are terminated (step 136 in Figure 11). Otherwise, there is time remaining and the monitoring process continues.

5 Those skilled in the art will appreciate that the time usage monitor 44 need not  
wait until no time remains on the account but rather may wait until the account is below  
a given threshold and give the client warnings. Alternatively, the time usage monitor  
10 may actually allow the time to go to slightly negative value and then terminate service at  
5 that point. Those skilled in the art will have known a number of different alternatives  
that may be provided for monitoring such usage. As was mentioned above, the usage  
need not be monitored purely as a value of time but also may be monitored as a  
15 monetary value or as another metric.

Eventually, the client completes usage of the services (step 98 in Figure 8). The  
10 client may subsequently again use the services provided by the web server 14 if time  
remains on the given account.  
20

The illustrative embodiment need not be practiced with a single client device at a  
single site as depicted in Figure 1. Rather mobile users may gain access to the web  
server 14 from multiple sites, such as depicted in Figure 12. In that example case, sites  
25 140, 142 and 144 are used to gain access to an account on the web server 14. The client  
uses different devices (i.e. device 146, device 148 and device 150).

While the present invention has been described with reference to an illustrative  
30 embodiment thereof, those skilled in the art will appreciate that various changes in form  
and detail may be made without departing from the intended scope of the present  
20 invention as defined in the appended claims. For example, the present invention need  
not use an ISP card but rather may simply relay account identifiers and authorization  
35 data to clients. The clients may be responsible for retaining such information. Still  
further, the present invention need not be practiced to gain access to Internet services but  
more generally may be used to gain access to web services on networks that include the  
40 25 Internet, an intranet or an extranet.

20

2. The method of claim 1 wherein the method further comprises refusing a  
user access to the services provided by the ISP when the monetary value of the account  
is less than a threshold amount.

25

3. The method of claim 1 wherein the account is not associated with any  
user.

30

4. The method of claim 1 further comprising providing a user with a set of  
information that contains an account identifier and authentication data for use in  
authenticating the user.

20

35

5. The method of claim 4 further comprising authenticating the user.

40

6. The method of claim 5 wherein authenticating the user entails receiving  
the account identifier and authentication data from the user.

25

45

7. The method of claim 4 further comprising the providing the user with a  
tangible record of an account identifier for the account.

30

8. The method of claim 7 wherein the tangible record is a card that is  
configured to be carried by the user.

50

55

5           9.     In a computing environment having a client device for use by a client and  
a web server for providing web services, a method comprising:

              providing a prepaid amount of web services that are available to that

10           client;

5               enabling the client to use the web services; and

              debiting the amount of web services available to the client based on how  
15           much the client used the web services.

10           10.    The method of claim 9 wherein the web services are services that provide  
access by the client to a network.

20           11.    The method of claim 9 wherein the web services are services that provide  
access by the client to an intranet.

25           12.    The method of claim 9 wherein the client is no longer enabled to use the  
web services when the amount of web services available to the client has been debited to  
30           a point where no amount of web services is available to the client.

20           13.    In a computing environment, a method comprising:

              providing a physical object to a user wherein said object includes  
35           information regarding a prepaid amount of services provided by an Internet  
Service Provider (ISP);

              receiving a request from the user to access the services provided by the  
40           ISP;

25               receiving at least some of the information included on the physical object  
from the user; and

              in response to receiving at least some of the information on the physical  
45           object, providing the services to the user until the prepaid amount of services has  
been consumed by the user.

30

50

55

5           14.    The method of claim 13 wherein the information included on the physical  
object includes an account identifier for an account with the ISP.

10           15.    The method of claim 13 wherein the information included on the physical  
5 object includes an indication of the prepaid amount of services.

15           16.    The method of claim 13 wherein the physical object is a card.

10           17.    The method of claim 16 wherein the card is a smart card.

20           18.    The method of claim 17 wherein the smart card contains electronic  
currency of the prepaid amount.

25           19.    The method of claim 18 further comprising paying for the services  
15 provided to the user by the ISP by transferring at least some of the electronic currency  
from the smart card.

30           20.    The method of claim 13 wherein the services comprise Internet access,

20           21.    The method of claim 13 wherein the services comprise access to a remote  
35 computing resource.

40           22.    In a computing environment having a client device for use by a client and  
25 a web server for providing web services, a computer-readable medium containing  
computer-executable instructions for performing a method comprising:  
              providing a prepaid amount of web services that are available to the  
              client;  
45               enabling the client to use the web services; and  
              debiting the amount of web services available to the client based on how  
30               much the client used the web services.

5                   23.    The computer-readable medium of claim 22 wherein the web services are  
services that provide access by the client to a network.

10                   24.    The computer-readable medium of claim 22 wherein the web services are  
5 services that provide access by the client to an intranet.

15                   25.    The computer-readable medium of claim 22 wherein the client is no  
longer enabled to use the web services when the amount of web services available to the  
client has been debited to a point where no amount of web services is available to the  
10 client.

20                   26.    In a distributed environment having multiple login sites where a user may  
login, a computer readable medium holding computer-executable instructions for  
performing a method, comprising:

25                   15                   providing a web services account for web services, wherein said account  
is authorized for a fixed amount of web services;  
enabling a user to access the web services via the account from a first of  
30 the login sites; and  
enabling a user to access the web services via the account from a second  
20 of the login sites.

35                   27.    The computer-readable medium of claim 26 wherein the method further  
comprises debiting the amount of web services for which the account is authorized based  
on a duration of access by the user.

40                   25                   28.    The computer-readable medium of claim 26 wherein the debiting is  
performed at a constant rate based upon duration of access by the user.

# INTERNATIONAL SEARCH REPORT

International Application No.

PCT/US 00/14119

## A. CLASSIFICATION OF SUBJECT MATTER

IPC 7 G07F7/02 G07F17/16

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 G07F H04M

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	DE 197 48 353 A (PIPELINE ONLINE-COM-SYSTEMS) 20 May 1999 (1999-05-20) abstract; claims; figures 1,2,5 column 5, line 6 -column 6, line 24 ---	1-10, 12-16,20
A		21-23, 25-28
A	WO 97 14118 A (SUNTEK SOFTWARE) 17 April 1997 (1997-04-17)  abstract; claims; figures page 8, line 10 -page 10, line 22 page 12, line 20 -page 13, line 10 --- -/--	1,2, 4-10, 12-23, 25-28

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

### \* Special categories of cited documents:

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document relating to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"A" document member of the same patent family
